

SkyPath — Family Traveller Persona

Persona profile • UX research synthesis • Family and child-aware travel booking

Persona type	Family / multi-passenger / child-aware traveller
Primary context	Family travel involving infants or young children, often across longer or unfamiliar journeys
Core motivation	Plan a comfortable, predictable trip while coordinating the needs of every family member
Key priorities	Child comfort, seating, baggage, meals, schedule, total cost, accommodation timing, booking confidence
Typical behaviour	Checks several connected travel details before committing and prefers to minimise surprises during the j

Persona Snapshot

The family traveller approaches booking as a coordination task involving the comfort, safety and practical needs of several people. When small children are travelling, decisions that might be secondary for an individual traveller—such as seating proximity, baggage, meals, arrival timing and access to suitable accommodation—can become central to the booking decision.

The traveller therefore looks beyond the flight price alone. They need confidence that the selected itinerary will work for the whole family, that important child-related requirements have been considered, and that the transition from airport to accommodation will be manageable.

Goals

- Find flights that work for the entire family and fit practical travel constraints.
- Keep parents and children seated together or understand available seating options.
- Understand baggage allowances, including family and child-related baggage requirements.
- Check available meal and food options, particularly for children or dietary needs.
- Coordinate flight arrival and departure times with accommodation check-in and check-out.
- Understand the overall cost of flights, seats, baggage, meals and relevant optional services.
- Review every passenger and family-related selection before payment.
- Keep the complete itinerary and important travel details accessible after booking.

Behaviours & Decision Patterns

- Considers the needs of children before finalising the flight.
- Checks whether seating arrangements will keep the family together.
- Pays close attention to baggage requirements because travelling with children can increase the amount of luggage carried.
- Considers meal availability and whether suitable food options are available during the journey.
- Evaluates arrival and departure times in relation to children's routines and accommodation check-in.
- May prefer a slightly more expensive or convenient option if it significantly reduces family stress.
- Reviews multiple details before payment because an error can affect the entire family.
- Values predictable information and clear confirmation more strongly when travelling with young children.

Pain Points

- Difficulty keeping a family group together during seat selection.
- Unclear information about child-related baggage or additional charges.
- Limited visibility of meal and food options before completing the booking.
- Difficulty understanding which services are available for children.
- Arrival times that create problems with accommodation check-in or family routines.
- Having to manage flight, meal, baggage and accommodation considerations across disconnected steps.
- Forms that make it easy to confuse one child or passenger with another.
- Unclear total pricing for the complete family booking.
- Limited visibility of important booking information after payment.

Needs from SkyPath

- Clear family and passenger grouping throughout the booking flow.
- Transparent seat availability and family seating information.
- Clear baggage allowances and associated costs.
- Visible meal and food-service information where available.
- Simple explanations of child-related travel services and restrictions.
- Strong visibility of arrival and departure times to support wider trip planning.
- A booking summary that shows the complete family cost and selected services.
- A clear review stage that reduces the risk of mistakes before payment.
- Accessible itinerary and post-booking information.

Design Implications

The Family Traveller highlights that a family booking is more than a collection of individual passenger records. The interface must support coordinated decisions while recognising that children introduce additional practical considerations. SkyPath should surface relevant information at the moment it becomes important without overwhelming the traveller.

Persona need	Design implication
Family coordination	Represent the booking at both group and individual-passenger levels.
Child-aware seating	Make family seating options, availability and any additional cost easy to understand.
Baggage planning	Clearly communicate baggage allowances and relevant child or family considerations.
Food and meals	Expose available meal or food-service information before the traveller reaches payment where possible.
Accommodation timing	Make arrival and departure times prominent so families can coordinate accommodation check-in and check-out.
Total cost	Maintain a visible total that reflects the complete family booking and selected services.
Error prevention	Use structured forms, clear passenger labels and validation to reduce mistakes.
Pre-payment confidence	Provide a comprehensive review of passengers, seats, baggage, meals and other selections.
Post-booking continuity	Keep itinerary and important family travel details accessible after confirmation.

Representative User Need

“Help me organise a comfortable and predictable trip for my family, especially when travelling with young children, without having to manage important details across too many separate steps.”

Role in the SkyPath Design

The Family Traveller acts as a secondary persona for evaluating multi-passenger and family-centred workflows. It strengthens the case for clear passenger grouping, family seating, baggage and meal information, transparent pricing, arrival-time visibility and a comprehensive review stage. Accommodation is treated as a connected trip-planning consideration rather than as a claim that SkyPath itself provides hotel booking. These needs can inform the information architecture, task flows, wireframes and final interface decisions developed later in the case study.
